Testovex: Pitch for Clients

Nov 4, 2026 · @Puneet Kamboj

Testovex is a no-code test automation platform with agents that cover the whole testing loop: they help write the tests, explain every failure, propose and verify the fix, file the bug, and tell you if you are ready to release. Your team spends its time on quality decisions, not on log digging and locator repair.

The problem every QA team recognises

- **Tests break every sprint.** A renamed class or moved button turns dozens of tests red, though nothing is wrong with the product.
- **Nobody knows why a run failed.** The first hour of every failure goes on working out whether it is a product bug, a changed element, a slow page or a down environment.
- **Coverage falls behind releases.** New stories ship faster than tests get written, so what is live in production is not what is covered.
- **Leaders fly blind.** Results sit in many tools, and "are we ready to ship?" is answered by gut feel.

What you get

Stage	What Testovex does	What it means for you
Create	Record in Chrome with no code, or generate tests from a URL, a user story, curl, Postman or OpenAPI. Test Author drafts tests from Jira stories and keeps them linked to each release.	A first working test in minutes, and coverage that keeps pace with what ships.
Run	Playwright on Chromium, Firefox and WebKit, in parallel, from the web app, the CLI or any CI pipeline. Data-driven runs use CSV, Excel, JSON or generated data.	One flow tested against many data sets, and a gate for your pipeline.
Understand	Failure Triage sorts every failure into product bug, changed element, timing or environment. Every run has video, screenshots and a trace.	Start from the answer, not the log.

Stage	What Testovex does	What it means for you
Fix	Self-Healing proposes a new locator from the live page. Autofix, when you turn it on, applies it, re-runs the test and keeps it only if it passes.	Less time repairing tests after UI changes.
Trust	Flaky detection and quarantine. Environment Doctor checks your app is up before a run starts.	A red build means something again.
Report	Bug Reporter drafts the Jira bug for your approval. Agent Inbox collects everything that needs a person.	From failed test to tracked bug in seconds.
Decide	Release Readiness gives ready, at risk or not ready for every project. Org dashboards show pass rate, failure causes and hours saved. Ask Your Tests answers questions in plain English.	Leaders get a clear answer without a spreadsheet.

How it works

1. **Connect.** Add your app URL and, if you use them, your Jira project and AI key. Setup takes minutes, with no infrastructure to run.
2. **Create.** Record a flow, or let Test Author and the generators draft tests for your team to review and approve.
3. **Run.** Tests run on every change, from the app or your pipeline, and every run records video, screenshots and a trace.
4. **Understand and fix.** Agents explain each failure, propose or apply verified fixes, and draft bug reports.
5. **Decide.** Release Readiness and the org dashboards show whether you are ready to ship.

At every step, a person stays in control: Self-Healing only suggests, Autofix is opt-in, and nothing reaches Jira until it is approved.

Benefits by role

Who	What changes
QA analysts and SDETs	Build and maintain tests without writing code. Spend less time repairing locators and investigating failures, and more on coverage.
QA leads and ACOE heads	One view across every project and team: pass rate, failure causes, flaky tests, time to fix, and a shared library of approved components.
Engineering and release managers	A ready, at risk or not ready verdict per project, runs that gate your pipeline, and Jira bugs drafted with the evidence attached.
Security and compliance	Each organization isolated by design, role-based access, locked credentials, and agents that can be switched off.

Built to be trusted

- **You stay in control.** Agents suggest, you approve. Autofix is opt-in per organization or project, and it keeps a change only if the re-run passes. One setting turns all agents off for an organization.
- **Your data stays yours.** Every organization is isolated from every other, and the agents never mix data across organizations. AI features use your own AI provider key.
- **Credentials are protected.** Org-level credentials are locked so test authors can use them but never read them, and Jira tokens are stored encrypted.
- **Everything is recorded.** Each agent action is logged on the run, and Agents Live shows what every agent did and why.
- **Live today.** All of the above runs in production now, in the beta. Formal certifications such as SOC 2 are on the roadmap, and a security questionnaire can be completed on request.

Start in minutes

Testovex is **free during the beta**, with no credit card needed. Beta founders also lock in **40% off any paid plan for the first year** and get a **free founder-led onboarding session** to set up the organization and record the first test together. Planned plans start at $49 per month per organization.

A good first step is a short pilot on one real project: connect the app, record or generate a handful of tests, and watch the agents handle the first failures. The Time Saved report then shows what the agents gave back.
